**NITRILASE (^) HOMOLOGS**  
THOMAS JEFFERSON UNIVERSITY

Inventor(s): CROCE, Carlo, M.

Application No. US9916366 US, Filed 19990720, A2 Published 20000127

**Abstract:** The present invention relates to nucleotide sequences of the *NIT1* gene and amino acid sequences of its encoded proteins, as well as derivatives and analogs thereof. Additionally, the present invention relates to the use (^) of nucleotide sequences of *NIT1* genes and amino acid sequences of their encoded proteins, as well as derivatives and analogs thereof and antibodies thereto, as diagnostic and therapeutic reagents for the detection and treatment of cancer. The present invention also relates to therapeutic compositions comprising Nit1 proteins, derivatives or analogs thereof, antibodies thereto, nucleic acids encoding the Nit1 proteins, derivatives, or analogs and *NIT1* antisense nucleic acids, and vectors containing the *NIT1* coding sequence.

## Detailed Description

**NITRILASE HOMOLOGS FIELD OF THE INVENTION** The present invention generally relates to the field of oncology and tumor suppressor genes, and more particularly to the structure and function of the NIT] gene, the structure of its encoded proteins, and the use of NIT] genes and the NIT] related genes and their encoded proteins and vectors containing the NIT] coding sequence as diagnostic and therapeutic reagents for the detection and treatment of cancer.

**15 BACKGROUND OF THE INVENTION** Introduction The present invention relates to nucleotide sequences of the NIT] gene and amino acid sequences of its encoded proteins, as well as derivatives and analogs thereof Additionally, the present invention relates to the use of nucleotide sequences of NIT] genes and amino acid sequences of their encoded proteins and vectors containing the NIT] coding sequence, as well as derivatives and analogs thereof and antibodies thereto, as diagnostic and therapeutic reagents for the detection and treatment of cancer. The present invention also relates to therapeutic compositions comprising Nitl proteins, derivatives or analogs thereof, antibodies thereto, nucleic acids encoding the Nitl proteins, derivatives, or analogs, and NIT] antisense nucleic acids, and vectors containing the NIT] coding sequence.

**Approaches to Elucidation and Characterization ofNITI** The tumor suppressor gene FHIT encompasses the common human chromosomal fragile site at 3p14.2 and numerous cancer cell bi-allelic deletions.

To study Fhit function, Fhit genes in *D. melanogaster* and *C. elegans* were cloned and characterized. The Fhit genes in both of these organisms code for fusion proteins in which the Fhit domain is fused with a novel domain showing homology to bacterial and plant nitrilases; the *D. melanogaster* fusion protein exhibited diadenosine triphosphate (ApppA) hydrolase activity expected of an authentic Fhit homolog.

In human and mouse, the nitrilase homologs and Fhit are encoded by two different genes, FHIT and NIT], localized on chromosomes 3 and I in human, and 14 and I in mouse, respectively. Human and murine NIT] genes were cloned and characterized, their exon-intron structure, their patterns of expression, and their alternative mRNA processing were determined.

The tissue specificity of expression of murine FHIT and NIT] genes was nearly identical. Typically, fusion proteins with dual or triple enzymatic activities have been found to carry out specific steps in a given biochemical or biosynthetic pathway; Fhit and Nitl, as fusion proteins with dual or triple enzymatic activities, likewise collaborate in a biochemical or cellular pathway in mammalian cells.

**Importance of MIT** The human FHIT gene at chromosome 3p14.2, spanning the constitutive chromosomal fragile site FRAM, is often altered in the most common forms of human cancer and is a tumor suppressor gene. The human FHIT gene is greater than one megabase in size encoding an mRNA of 1.1 kilobases and a protein of 147 amino acids.

The rearrangements most commonly seen are deletions within the gene.

These deletions, often occurring independently in both alleles and resulting in inactivation, have been reported in tumor-derived cell lines and primary tumors of lung, head and neck, stomach, colon, and

other organs. In cell lines derived from several tumor types, DNA rearrangements in the FHIT locus correlated with RNA and/or Fhit protein alterations.

Because the inactivation of the MIT gene by point mutations has not been demonstrated conclusively and because several reports have shown the amplification of aberrant-sized MIT reverse transcription-PCR (RT-PCR) products from normal cell RNA, a number of investigators have suggested that the MIT gene may not be a tumor suppressor gene. On the other hand it has been reported that re-expression of Fhit in lung, stomach and kidney tumor cell lines lacking endogenous protein suppressed tumorigenicity *in vivo* in 4 out of 4 cancer cell lines. This suggests that MIT is indeed a tumor suppressor gene. It is noted that a report has suggested that Fhit enzymatic activity is not required for its tumor suppressor function.

Fhit protein is a member of the histidine triad (HIT) superfamily of nucleotide binding proteins and is similar to the *Schizosaccharomyces pombe* diadenosine tetraphosphate (AP4A) hydrolase. Additionally it has been reported that, *in vitro*, Fhit has diadenosine triphosphate (ApppA) hydrolase enzymatic activity.

Neither the *in vivo* function of Fhit nor the mechanism of its tumor suppressor activity is known. Nonetheless, genetic, biochemical and crystallographic analysis suggest that the enzyme- substrate complex is the active form that signals for tumor suppression. One approach to investigate function is to investigate Fhit in model organisms such as *Drosophila melanogaster* and *Caenorhabditis elegans*.

The present invention involves the isolation and characterization of the NIT] gene in these organisms. Fhit occurs in a fusion protein, Nit-Fhit, in D.

*melanogaster* and *C. elegans*, but FHIT and NIT] are separate genes in mammalian cells. The human and mouse NIT] genes are members of an uncharacterized mammalian gene family with homology to bacterial and plant nitrilases, enzymes which cleave nitriles and organic amides to the corresponding carboxylic acids plus ammonia.

**SUMMARY OF THE INVENTION** Accordingly, it is an object of the present invention to purify a NIT] gene.

It is a further object of the present invention to purify a NIT] gene, wherein the purified gene is a human gene.

It is an object of the present invention to purify a NIT1 gene, wherein the purled gene is a mammalian gene.

It is an object of the present invention to purify a Nitl protein.

It is another object of the present invention to purify a Nitl protein, wherein the purified protein is a human protein.

It is another object of the present invention to purify a Nitl protein, wherein the purified protein is a mammalian protein.

Yet another aspect of the present invention is a purified protein encoded by a nucleic acid having a nucleotide sequence consisting of the coding region of SEQ ID NO: I (Figure 6).

Another aspect of the present invention is an antibody capable of binding a Nitl protein.

It is another object of the present invention to isolate a nucleic acid of less than 100 kb, comprising a

nucleotide sequence encoding a Nit I protein.

Another object of the present invention is a pharmaceutical composition comprising a therapeutically effective amount of a NitI protein; and a therapeutically acceptable carrier.

Another object of the present invention is a method of treating or preventing a disease or disorder in a subject comprising administering to said subject a therapeutically effective amount of a molecule that inhibits NitI function.

#### ANOTHER ASPECT

Another aspect of the present invention is a method of treating or preventing a disease or disorder in a subject comprising administering to said subject a therapeutically effective amount of a molecule that enhances NitI function.

It is yet another aspect of the present invention to diagnose or screen for the presence of or a disposition for developing a disease in a subject, comprising detecting one or more mutations in NIT] DNA, RNA or NitI protein derived from the subject in which the presence of said one or more mutations indicates the presence of the disease or disorder or a predisposition for developing the disease or disorder.

It is yet another aspect of the present invention to treat a disease or disorder with a vector containing the coding segment of the NIT] gene.

BRIEF DESCRIPTION OF THE DRAWINGS Fig. 1. A sequence comparison of human, murine, D. melanogaster, and C.

elegans NitI and Fhit proteins. Identities are shown in black boxes, similarities are shown in shaded boxes. For human and mouse FHIT GenBank accession numbers are U46922 and AF047699, respectively.

Fig. 2. Northern blot analysis of expression of NIT] and FHIT mRNAs in murine and human tissues, as well as in D. melanogaster, and C elegans. (A) Mouse multiple tissues Northern blot. Lanes 1-8: heart, brain, spleen, lung, liver, skeletal muscle, kidney, and testis. (Top) Fhit probe; (Middle) Nit] probe; (Bottom) actin probe. (B) Human blot, NIT] probe. Lanes 1-8: heart, brain, placenta, lung, liver, skeletal muscle, kidney, and pancreas. (C) Lanes 1 and 2: D.

melanogaster adult, D. melanogaster embryo; D. melanogaster Nit-Fhit probe.

Lane 3: C. elegans adult; C. elegans Nit-Fhit probe.

Fig. 3. Genomic organization of human and murine NIT] genes and D.

melanogaster and C. elegans Nit-Fhit genes. (A) Exon-intron structure of the genes. (B) Alternative processing of human NIT] gene.

Fig. 4. Cleavage of ApppA by D. melanogaster Nit-Fhit. At indicated times of incubation, samples were spotted on TLC plates with appropriate nucleotide standards.

Fig. 5. Analysis of alternative transcripts of human NIT] by RT-7PCR. RT- PCR of HeLa RNA was performed with primers in different exons. Lanes 1- 6:

exons I and 3 (transcript 2); exons 1C and 3 (transcript 5); exons I A and 3 (transcripts 3, upper band and 4, lower band); exons 2 and 3 (transcripts 2-4); exons I and I C (transcript 5); and exons I and 2 (transcript 2).

Fig. 6. Highly conserved sequence of human, murine, D. melanogaster, and C elegans NIT] gene. (SEQ ID NO: 1).

**DETAILED DESCRIPTION** Genomic and cDNA clones One million plaques of a mouse genomic library (bacteriophage library from strain SVJ129, Stratagene, La Jolla, CA) and one hundred thousand plaques of a D. melanogaster genomic library were screened with corresponding cDNA probes. Clones were purified and DNA was isolated. Sequencing was carried out using Perkin Elmer thermal cyclers and ABI 377 automated DNA sequencers.

DNA pools from a human BAC library (Research Genetics, Huntsville, AL) were screened by PCR with NIT] primers (TCTGAAACTGCAGTCTGACCTCA (SEQ ID NO:2) and CAGGCACAGCTCCCTCACTT (SEQ ID NO:3)) according to the supplier's protocol. The DNA from the positive clone, 31KI1, has been isolated using standard procedures and sequenced. Chromosomal localization of the human NIT] gene was determined using a radiation hybrid mapping panel (Research Genetics) according to the supplier's protocol and with the same primers as above. To map murine Nit] gene, Southern blot analysis of genomic PHXM. ph DNA from progeny of a (AEJIGn-a bpHla b spretus)F I x AEJIGn-a b /a bh P backcross was performed using a full length murine Nit] cDNA probe. This probe detected a unique 2.0 kb Dral fragment in AEJ DNA and a unique 0.75 kb fragment in M. spretus DNA. Segregation of these fragments were followed in D 180 N2 offspring of the backcross. Additional Mit markers (DIM04, DIM35, and DJMit209) were typed from DNA of 92 mice by using PCR consisting of an initial denaturation of 4 minutes at 94°C followed by 40 cycles of 94°C for 30 seconds, 55°C for 30 seconds and 72°C for 30 seconds. Linkage analysis was performed using the computer program SPRETUS MADNESS: PART DEUX.

Human and mouseNITI expressed sequence tag (EST) clones were purchased from Research Genetics. The sequences of human and murine NIT] genes and cDNAs and D. melanogaster and C. elegans Nit-Fhit cDNAs have been deposited in GenBank.

In situ hybridization D. melanogaster polytene chromosome spreads were prepared from salivary glands of third-instar larvae as described. NitFhit DNA fragments were labeled with digoxigenin-11-dUTP using a random-primed DNA labeling kit (Boehringer Mannheim, Indianapolis, IN), and were used as probes for the chromosomal in situ hybridization. Hybridization was for 20 hours at 37°C in hybridization buffer: 50% formamide, 2x standard saline citrate (SSC), 10% dextran sulfate, 400 mg/ml salmon sperm DNA. Antidigoxigenin-fluorescein antibodies (Boehringer Mannheim) were used for detection of hybridizing regions.

DNA was counterstained with Hoechst 33258 (Sigma, St. Louis, MO). The slides were analyzed by fluorescence microscopy. For in situ hybridization, embryos were fixed and processed as described previously, except that single-stranded RNA probes were used. Full length NitFhit cDNA was cloned into BluescriptII KS+ vector and used to synthesize antisense RNA probes with the Genius 4 kit (Boehringer Mannheim).

**RT-PCR, Northern and RACE analysis** Human and mouse multiple tissue northern blots (Clontech, Palo Alto, CA) were hybridized with corresponding NIT] cDNA probes and washed using the supplier's protocol. For the HeLa cell line, total RNA was isolated from 1-5 x 10<sup>8</sup> cells using Trizol reagent (Gibco BRL, Gaithersburg, MD). D. melanogaster PolyA+ RNA was purchased from Clontech. Three ~10 µg of polyA+ RNA or 15 µg of total RNA were electrophoresed in 0.8% agarose in a borate buffer containing formaldehyde, transferred to HybondN+ membrane (Amersham, Arlington Heights, IL) using standard procedures and hybridized as described above. For RT-PCR, 200 ng of polyA+ RNA or 3 ~10 µg of total RNA were treated with DNaseI (amplification grade, Gibco BRL) following the manufacturer's protocol. DNase-treated RNA was used in reverse transcription (RT) reactions as follows: 10 nM each dNTP, 100 pmol random hexamers (oligo (dT) priming was used in some cases), DNaseI treated RNA, and 200 units of murine leukemia virus (MuLV) reverse transcriptase (Gibco

BRL), in total volume of 20  $\mu$ l were incubated at 42°C for 1 hour followed by the addition of 10  $\mu$ g RNase A and incubation at 37°C for 30 min. One  $\mu$ L of the reaction was used for each PCR reaction. PCR reactions were carried out under standard conditions using 10 pmoles of each gene-specific primer and 25-35 cycles of 95' 30", 55-60' 30", 72' 1'. Products were separated on 1.5% agarose gels and sometimes isolated and sequenced or cloned and sequenced. Oligo (dT)-primed double-stranded cDNA was synthesized by using procedures and reagents from the Marathon RACE cDNA amplification kit (Clontech); the cDNA was ligated to Marathon adapters (Clontech). 3' and 5' RACE products were generated by long PCR using gene-specific primers and the API primer (Clontech). To increase the specificity of the procedure, the second PCR reaction was carried out by using nested gene-specific primers and the AP2 primer (Clontech). PCR reactions were performed according to the Marathon protocol using the Expand long template PCR system (Boehringer Mannheim) and cycles of 94' 30", 60' 30", 68' 4'. RACE products were electrophoresed, identified by hybridization and sequenced. Degenerate FHIT primers were:

GTNGTNCCNGGNCAYGNTNGT (SEQ ID NO:4) and ACRTGNACRTGYTTNACNGTYTGNGC (SEQ ID NO:5). D. Melanogaster Fhit RACE and RT-PCR primers were: GCGCCTTGTGGCCTCGACTG (SEQ ID NO:6) and CGGTGGCGGAAGTTGTCTGGT (SEQ ID NO:7). C. elegans Fhit RACE and RT-PCR primers were: GTGGCGGCTGCTAAACTGG (SEQ ID NO: 8) and TCGCGACGATGAACAAGTCGG (SEQ ID NO: 9). Human NIT] RT-PCR primers were: GCCCTCCGGATCGGACCCT (SEQ ID NO:10) (exon 1); GACCTACTCCCTATCCCGTC (SEQ ID NO: 11) (exon I a); GCTGCGAAGTGCACAGCTAAG (SEQ ID NO: 12) and AAACTGAAGCCTTTCCCTCTGAC (SEQ ID NO:13) (exon Ic); TGGGCTTCATCACCAGGCCT (SEQ ID NO: 14) and CTGGGCTGAGCACAAAGTACTG (SEQ ID NO: 15) (exon 2); GCTTGTCTGGCGTCGATGTTA (SEQ ID NO: 16) (exon 3).

**Protein expression and enzymatic characterization** The NIT-FHIT cDNA was amplified with primers TGACGTCGACATATGTCAAATCTAGTTAACCAACG (SEQ ID NO: 17) and TGGGTACCTCGACTAGCTTATGTCC (SEQ ID NO: 18), digested with NdeI and KpnI, and cloned into plasmid pSGA02 as a NdeI-KpnI fragment.

Escherichia coli strain SGIOO transformants were grown in Luria-Bertani with 100  $\mu$ g/ml of ampicillin and 15  $\mu$ g/ml of chloramphenicol at 15°C. When the culture reached an optical density (600 nm) of 0.25, isopropyl B-D- thiogalactoside was added to a final concentration of 200 pM. NitFhit protein was purified from inclusion bodies as described. Briefly, the cell pellet from a 1-liter culture was resuspended in 50 ml of 20 mM Tris-HCl (pH 7.5), 20% sucrose, 1 mM EDTA and repelleted. Outer cell walls were lysed by resuspension in ice-water. Spheroblasts were pelleted, resuspended in 140 mM NaCl, 2.7 mM KCl, 12 mM Na-P04 (pH 7.3), 5mM EDTA, 500mM phenylmethylsulfonyl fluoride, 1  $\mu$ g/ml leupeptin and ~10  $\mu$ g/ml of aprotinin, and sonicated. The resulting inclusion body preparation was washed and solubilized in 5 M guanidinium hydrochloride, 50mM Tris- HCl (pH 8.0), 5mM EDTA. Soluble NitFhit protein was added dropwise to 250ml of 50mM Tris-HCl (pH 8.0), 1mM DTT, 20% glycerol at 40°C. After a 14 hour incubation, the 13-kg supernatant was concentrated 100-fold with a Centricon filter. A 1 -liter culture yielded approximately 200  $\mu$ g of partially purified, soluble NitFhit. ApppA hydrolase activity was assayed at 30°C in 20  $\mu$ l of 50nm Na-HEPES pH 7.5, 10% glycerol, 0.5 mM MnCl<sub>2</sub>, 4mM ApppA, 1  $\mu$ M NitFhit.

TLC plates were developed as described.

**Cloning and characterization of D. melanogaster and C. elegans Fhit homologs** To obtain D. melanogaster Fhit sequences, degenerate primers were designed in the conserved regions of exons 5 and 7 of human FHIT. RT-PCR experiments with these primers and D. melanogaster RNA resulted in an ~200 bp product, which when translated showed ~50% identity to human Fhit protein. This sequence was used to design specific D. melanogaster Fhit primers. 5' and 3' RACE with these primers resulted in ~1.5 kb full length cDNA (including polyadenylation signal and Poly(A) tail) encoding a 460 amino acid

protein with a 145 amino acid C-terminal part homologous to human Hit (40% identity and 47% similarity) and a 315 amino acid N-terminal extension (Fig. 1). Northern analysis (Fig. 2C) showed a single band of ~1.5 kb in both embryo and adult D.

melanogaster confirming that the full length cDNA has been cloned.

The 460 amino acid predicted protein sequence was used in a BLASTP search. Of the top 50 scoring alignments, 22 aligned with the 145 residue C-terminal segment (17 hit-related sequences) and 28 aligned with the 315 residue N-terminal segment. The 28 sequences aligning with the N-terminus were led by an uncharacterized gene from chromosome X of *Saccharomyces cerevisiae* ( $P$ -value of  $1.4 \times 10^{-41}$ ), followed by uncharacterized ORFs of many bacterial genomes and a series of enzymes from plants and bacteria that have been characterized as nitrilases and amidases. Thus, the 460 amino acid predicted protein contains an N-terminal nitrilase domain and a C-terminal Fhit domain and was designated NitFhit.

The *D. melanogaster* Nit-Fhit cDNA probe was used to screen a *D.*

*melanogaster* lambda genomic library. Sequencing of positive clones revealed that the gene is intronless and, interestingly, the 1.5-kb Nit-Fhit gene is localized within the 1.6-kb intron I of the *D. melanogaster* homolog of the murine glycerol kinase (Gyk) gene. The direction of transcription of the Nit-Fhit gene is opposite to that of the Gyk gene (Fig. 3A). It is not known if such localization affects transcriptional regulation of these two genes.

The cytological position of the Nit-Fhit gene was determined by in situ hybridization to salivary gland polytene chromosomes. These experiments showed that there is only one copy of the sequence which was localized to region 61A, at the tip of the left arm of chromosome 3. Digoxigenin-labeled RNA probes were hybridized to whole-mount embryos to determine the pattern of expression during development. Nit-Fhit RNA was uniformly expressed throughout the embryo suggesting that NitFhit protein could be important for most of the embryonic cells.

Because human Fhit protein and the *D. melanogaster* Fhit domain were only 40% identical, to show that the authentic *D. melanogaster* Fhit homolog was cloned, its enzymatic activity was tested. Fig. 4 shows that recombinant D.

*melanogaster* NitFhit is capable of cleaving ApppA to AMP and ADP and therefore possesses ApppA hydrolase activity.

*C. elegans* Fhit genomic sequences were obtained from the Sanger database (contig Y56A3) by using BLAST searches. 5' and 3' RACE with *C. elegans* Fhit specific primers yielded a 1.4-kb cDNA (including polyadenylation signal and Poly(A) tail) coding for a 440 amino acid protein (Fig. 1). Northern analysis (Fig. 2Q) showed a single band of a similar size in adult worms. Similarly to *D.*

*melanogaster*, the *C. elegans* protein contained an N-terminal nitrilase domain and a C-terminal Fhit domain (Fig. 1) with 50% identity and 57% similarity to human Fhit. Comparison between *C. elegans* Nit-Fhit cDNA and genomic sequences from the Sanger database revealed that the *C. elegans* Nit-Fhit gene comprises 8 exons and is more than 6.5 kb in size (Fig. 3A); the nitrilase domain is encoded by exons 1-6, and the Fhit domain is encoded by exons 6-8. *D. melanogaster* and *C.*

*elegans* NitFhit proteins are 50% identical and 59% similar and exhibit several conserved domains (Fig. 1).

Cloning and characterized of human and murine NIT cDNAs and genes Because Fhit and nitrilase domains are part of the same polypeptides in *D.*

nielanogaster and *C. elegans*, it is reasonable to suggest that they may be involved in the same biochemical or cellular pathway(s) in these organisms. Because nitrilase homologs are conserved in animals, the mammalian nitrilase homologs were cloned as candidate Fhit-interacting proteins.

To obtain human and murine NIT] sequences, the *D. melanogaster* nitrilase domain sequence was used in BLAST searches of the GenBank EST database.

Numerous partially sequenced human and murine NIT] ESTs were found. All mouse Nit] ESTs were identical, as were all human NIT] ESTs, suggesting the presence of a single NIT] gene in mouse and human. To obtain the full-length human and mouse cDNAs, several human and mouse ESTs and human 5' and 3' RACE products were completely sequenced. This resulted in the isolation of a

-1.4-kb full-length human sequence encoding 327 amino acids and a -1.4- kb mouse full-length sequence coding for 323 amino acids (Fig. 1), although several alternatively spliced products were detected in both cases (see below and Fig. 3B).

Both cDNAs are polyadenylated, but lack polyadenylation signals, although AT- rich regions are present at the very 3' end of each cDNA. Mouse and human Nitl amino acid sequences were 90% identical; the human Nitl amino acid sequence was 58% similar and 50% identical to the *C elegans* nitrilase domain and 63% similar and 53% identical to the *D. melanogaster* nitrilase domain (Fig. 1).

Murine lambda and human BAC genomic libraries were screened with the corresponding NIT] cDNA probes, yielding one mouse lambda clone and one human BAC clone containing the NIT] genes. The human and murine NIT] genomic regions were sequenced and compared to the corresponding cDNA sequences. The genomic structure of human and mouse NIT] genes is shown in Fig. 3A. Both genes are small: the human gene is -3.2 kb in size and contains 7 exons; the murine gene is -3.6 kb in size and contains 8 exons. Southern analysis confirmed that both human and mouse genomes harbor a single NIT] gene.

A radiation hybrid mapping panel (GeneBridge 4) was used to determine the chromosomal localization of the human NIT] gene. By analysis of PCR data at the Whitehead/MIT database (<http://www-cenome.wi.mit.edu>), the NIT] gene was localized 6.94 cR from the marker CHLC.GATA43AO4, which is located at 1q21- I q22.

A full length murine Nit] cDNA probe was used to determine the chromosomal location of the murine gene by linkage analysis. Interspecific backcross analysis of 180 N2 mice demonstrated that the Nit] locus cosegregated with several previously mapped loci on distal mouse chromosome 1. The region to which Nit] maps was further defined by PCR of genomic DNA from 92 N2 Mice using the markers DIM04, DIM05 and DIMit209 (Research Genetics). The following order of the genes typed in the cross and the ratio of recombinants to N2 mice was obtained: centromere - DIM04 - 7/78 - DIM05 - 8/90 - Nit] - 11/91 - D-Mit209 - telomere. The genetic distances given in centiMorgans (nS.E.) are as follows: centromere - DIMit209 - 9.0 n 3.2 - DJMit35 - 8.9 n 3.0 - Nit] - 12.1 n 3.4 - DIMit209 - telomere. This region of mouse chromosome I (1q21 - 1q23) is syntenic to human chromosome 1q and is consistent with the localization of the human ortholog of Nit].

Expression and alternative splicing of hunian and murine Nit] genes For the human gene, Northern analysis revealed two major transcripts of

-1.4 kb and -2.4 kb in all adult tissues and tumor cell lines tested. A third band of

-1.2 kb was observed in adult muscle and heart (Fig. 2B). The longest cDNA (-1.4 kb) corresponds to the -1.4-kb transcript observed on Northern blots. The 1.2-kb band corresponds to transcript I on Fig. 3B (see below). It is not known if the -2.4-kb RNA represents an additional transcript or an incompletely

processed mRNA. No significant variation in human NIT] mRNA levels was observed in different tissues (Fig. 2B). On the contrary, different mouse tissues showed different levels of expression of Nit] mRNA (Fig. 2A). The highest levels of Nit] mRNA were observed in mouse liver and kidney (Fig. 2A, Middle, lanes 5 and 7).

Interestingly, the pattern of Nit] expression was almost identical to the pattern of the expression of Fhit (Fig. 2A, Top and Middle), supporting the hypothesis that the proteins may act in concert or participate in the same pathway.

Analysis of mouse Nit] ESTs revealed that some transcripts lack exon 2 and encode a 323 amino acid protein. An alternative transcript containing exon 2 encodes a shorter, 290 amino acid protein starting with the methionine 34 (Fig. 1).

Analysis of human ESTs and 5' RACE products from HeLa and testis also suggested alternative processing. To investigate this, a series of RT- PCR experiments was carried out. Fig. 5 shows the results obtained from HeLa RNA (similar results were obtained using RNAs from the MDA-MB-436 breast cancer cell line and adult liver). The alternatively spliced transcripts are shown on Fig.

3B. Transcript 1, lacking exon 2, was represented by several ESTs in the Genbank EST database. This transcript probably corresponds to the -1.2-kb transcript observed on Northern blots in adult muscle and heart. Transcript 2 encoding the 327 amino acid Nitl protein (Fig. 1) is a major transcript of human NIT] at least in the cell lines tested. This transcript lacks exons 1a and 1b. Transcript 3 has exon I a and I b; transcript 4 has exon I a but lacks exon 1 b (Fig. 3B). It is not known if transcript 5 (lacking exon 2) starts from exon I or 1c.

The alternative initiating methionines of different transcripts are shown on Fig. 3B. Data suggest that at least in COS-7 cells transfected with a construct containing transcript 2, the methionine in exon 3 (shown in transcripts 1 and 3, Fig. 3B) initiates more efficiently than the methionine in exon 2 (Fig. 3B, transcript 2).

**Discussion** Although the frequent loss of Fhit expression in several common human cancers is well documented, and results supporting its tumor suppressor activity have been reported, the role of Fhit in normal and tumor cell biology and its mechanism of its action *in vivo* are unknown. The AP3A hydrolytic activity of Fhit seems not to be required for its tumor suppressor function, and it has been suggested that the enzyme-subtract complex is the active form of Fhit. To facilitate an investigation of Fhit function, a model organisms approach was initiated by cloning and characterization of *D. melanogaster* and *C. elegans* Fhit genes.

Surprisingly, in flies and worms, Fhit is expressed as a fusion protein with the Fhit domain fused into a "Nit" domain showing homology to plant and bacterial nitrilases. Human and murine NIT] genes were further isolated. Nit and Fhit are expressed as separate proteins in mammals but, at the mRNA level, are coordinately expressed in mouse tissues.

In several eukaryotic biosynthetic pathways multiple steps are catalyzed by multifunctional proteins containing two or more enzymatic domains. The same steps in prokaryotes frequently are carried out by monoenzymatic proteins that are homologs of each domain of the corresponding eukaryotic protein. For example, Gars, Gart and Airs are domains of the same protein in *D. melanogaster* and mammals. These domains catalyze different steps in de novo synthesis of purines.

In yeast, Gart homolog (Ade8) is a separate protein and Gars and Airs homologs (Ade5 and Ade7) are domains of a bienzymatic protein; in bacteria, all three homologs (PurM, PurN and PurI) are separate proteins. De novo pyrimidine biosynthesis illustrates a similar case. Recently, a fusion protein of a lipoxygenase and catalase, both participating in the metabolism of fatty acids, has been identified in

corals. In all of these examples, if domains of a multienzymatic protein in some organisms are expressed as individual proteins in other organisms, the individual proteins participate in the same pathways. This observation and the fact that Fhit and Nitl exhibit almost identical expression patterns in murine tissues suggest that Fhit and Nitl participate in the same cellular pathway in mammalian cells.

## Claims

### WHAT IS CLAIMED IS:

1. A purified NIT] gene.
2. The gene of claim 1 which is a human gene.
3. The gene of claim 1 which is a mammalian gene.
4. A purified Nitl protein.
5. The protein of claim 4 which is a human protein.
6. A purified protein encoded by a nucleic acid having a nucleotide sequence consisting of the coding region of SEQ ID NO: 1.
7. An antibody which is capable of binding a Nitl protein.
8. The antibody of claim 7 which is monoclonal.
9. A molecule comprising a fragment of the antibody of claim 7, which fragment is capable of binding a Nit I protein.
10. An isolated nucleic acid of less than 100 kb, comprising a nucleotide sequence encoding a Nitl protein.
11. The nucleic acid of claim 10 in which the Nit I protein is a human Nit I protein.
12. A pharmaceutical composition comprising a therapeutically effective amount of a Nitl protein; and a therapeutically acceptable carrier.
13. A method of treating or preventing a disease or disorder in a subject comprising administering to said subject a therapeutically effective amount of a molecule that inhibits Nitl function.
14. A method of treating or preventing a disease or disorder in a subject comprising administering to said subject a therapeutically effective amount of a molecule that enhances Nitl function.
15. A method of diagnosing or screening for the presence of or a predisposition for developing a disease or disorder in a subject comprising detecting one or more mutations in NIT] DNA, RNA or Nit l protein derived from the subject in which the presence of said one or more mutations indicates the presence of the disease or disorder or a predisposition for developing the disease or disorder.
16. A method of treating or preventing a disease or disorder in a subject by using a vector containing the NIT] gene coding sequence.
